Chapter 1

Thurs Sept 10: Syllabus

1.1   Instructor Information

Instructor: Dr. Amy Hurford
Office: Teaching remotely
Email: ahurford@mun.ca
I will try to reply to emails within 24 hours (excluding weekends and holidays).
Outside of work hours, I am frequently unable to reply. I am always available
during the lecture times. Please email to request a meeting for a different time.

1.2   Course Information

TR 12.00-12.50pm
F 1-1.50pm
WebEx links appear in the course materials on each relevant day
Course description: Population and Evolutionary Ecology is an introduction
to the theory and principles of evolutionary ecology and population dynamics.
Pre-requisites: BIOL 2600; at least one of BIOL 2010, 2122 or 2210.

Course format:
The course has been re-designed for online delivery. Specifically, no exams that
require invigilation are part of the grading scheme because these are challenging
to invigilate remotely. Pre-recorded lectures limit my ability to interact with
students. Therefore, I have elected to dedicate all lecture time to answering your
questions. For each day of 'lecture' there is a list of questions you are required
to answer and hand-in, ideally before the next class, but you have up to a week
to submit your answers. There is also list of readings, that if completed, will

allow you to answer the questions. Prior to 'lectures' you should complete the required readings, and I can most effectively help you if you have read over the questions ahead of time.

Course expectations: Any students that are disruptive, violating university policies, or acting in a potentially unsafe way will be warned and asked to leave.

Learning goals I consider your completed assignments to be a portfolio of your knowledge in population and evolutionary ecology. You will also get some exposure to coding in R. It takes a while to become proficient in a programming language, but all the time you spend coding helps you towards becoming proficient. Some students may enjoy this aspect of the course and subsequently continue to build their programming abilities. The content emphasizes a deeper understanding of fewer concepts, and building your ability to learn more on your own.

1.3 Required Text and Resources

The course materials are all (here)[].

Late assignments, labs, and missed midterms, and final exams will be accommodated as described by University Regulation 6.7.3 and 6.7.5 (see https://www.mun.ca/regoff/calendar/sectionNo=REGS-0474 for Regulations). The Final exam will cover all Lecture material and readings, but not Labs. Specific regulations governing final examinations are described by University Regulation 6.8. Lecture participation is highly recommended and practice problems completed during lectures may appear on Assignments.

Additional Policies Accommodation of students with disabilities Memorial University of Newfoundland is committed to supporting inclusive education based on the principles of equity, accessibility and collaboration. Accommodations are provided within the scope of the University Policies for the Accommodations for Students with Disabilities (www.mun.ca/policy/site/policy.php?id=239). Students who may need an academic accommodation are asked to initiate the request with the Glenn Roy Blundon Centre at the earliest opportunity (www.mun.ca/blundon).

Academic misconduct Students are expected to adhere to those principles, which constitute proper academic conduct. A student has the responsibility to know which actions, as described under Academic Offences in the University Regulations, could be construed as dishonest or improper. Students found guilty of an academic offence may be subject to a number of penalties commensurate with the offence including reprimand, reduction of grade, probation, suspension or expulsion from the University. For more information regarding this policy, students should refer to University Regulation 6.12.

Equity and Diversity A safe learning environment will be provided for all students regardless of race, colour, nationality, ethnic origin, social origin, religious creed, religion, age, disability, disfigurement, sex (including pregnancy), sexual orientation, gender identity, gender expression, marital status, family status, source of income or political opinion.

You should not photograph or record myself, teaching assistants, or other students in the class without first obtaining permission. Accommodation will be made for students with special needs.

The sound should be turned off on phones and computers during class.

Additional Supports Resources for additional support can be found at: • www.mun.ca/currentstudents/student/ • https://munsu.ca/resource-centres/

The last day to drop the course without academic prejudice is Wednesday Nov. 4.

1.4 Grading

- 27 assignments - 50%
- Midterm - 15%
- Final Project - 35%

1.5 Handing in your work

1.5.1 Making figures to hand-in

The graphs you hand in need to have descriptive axeses and a figure caption. You may put these elements together using a word processing software such as *Microsoft Word.*

1.5.2 Writing R scripts to hand-in

To write your own R scripts follow the guidelines described in Chapter 7 Best Practices of *Quantitative training in Biology.* If you are asked to hand in your R script this means you need to submit an `.R` file to your dropbox on brightspace.

Chapter 2

Friday Sept 11: Sept What is a population?

Submit your answers to the Questions to Brightspace.

2.1 To hand-in

1. Give a definition of a population from a textbook or peer-reviewed publication. Provide the citation.

2. Write 1 paragraph describing why the definition of a population matters?

3. Find a peer-reviewed paper where a population is studied. Write 1 paragraph discussing how a population is defined in the study.

2.2 Resources

Chapter 3

Tues Sept 15: Exponential growth - discrete time

3.1 Required reading

Vandermeer, J.H., Goldberg, D.E., 2013. Population Ecology: First Principles (Second Edition). Princeton University Press, Princeton, United States. p1-3. Link

3.2 Questions

Submit your answers to Brightspace

1. Let $\lambda = 5$ in equation (3) (see the required reading). Explain the meaning of $\lambda = 5$.

2. Suppose the number of lilypads during week 7 is 150. Let $\lambda = 5$, and assume that the units of t are weeks. Use equation (3) to calculate the number of lilypads in week 8.

3. Use your answer to question 2. to calculate the number of lilypads in week 9.

4. Equation (4) for the required reading assumes that $N_0 = 1$, however, this formula can be generalized such that

$$N_t = N_0\lambda^t$$

where N_t is the population size at time, t. Define time such that $t = 0$ is week 7 and t is then the number of weeks since week 7. Use the the equation above to answer question 3 and confirm that the answer is the same (i.e., find the population size for week 9, when $\lambda = 5$ and the population size for week 7 is 150).

5. Use the formula from question 4 to find the population size for week 15, where N_0 and λ are the same as question 4.

6. It is important to note that all mathematical formulas should have the same units on both sides of the equals sign and for each term that is added or subtracted. The units of the population size, N_t, at time, t, are number. The geometric growth rate, λ is unitless. Choose a formula from the required reading and give the units for each of the terms to show that both sides of the equals have the same units. For example, for the equation that appears in question 4, we have:

$$
\begin{aligned}
N_t &= N_0\lambda^t \\
\text{(number)} &= \text{(number)(unitless)}^{weeks} \\
\text{(number)} &= \text{(number)}
\end{aligned}
$$

Note that:

$$
\begin{aligned}
\text{(unitless)} \times \text{(quantity with units)} &= \text{(quantity with units)} \\
\text{(unitless)}^{\text{(quantity)}} &= \text{(unitless)}
\end{aligned}
$$

7. Although not stated in the reading, $\lambda = 1 + b - d$ where b is the per capita birth rate over one time step (i.e. one week for this example), and d is the fraction of the lilypad population that dies over one time step. The number 1 is considered unitless, what must the units of b and d be?

8. In the reading, $\lambda = 2$. Given that $\lambda = 1 + b - d$, what are some possible values of b and d.

9. [True or False] For discrete time exponential growth (as per the reading), the change in population size from one week to the next depends not so much on the per capita birth rate, but on the difference between the per capita birth rate and the per capita death rate.

Chapter 4

Thurs Sept 17: Getting started with R

4.1 Required reading

You are required to read and complete all the exercises in Chapters 1 *Introduction*, 3 *R and RStudio*, and 4 *Finding your way around RStudio* of:

Quantitative skills for biology https://ahurford.github.io/quant-guide-all-courses/

When you are finished you should have `R` and `RStudio` installed on your computer, or you should be familar with running `RStudio Cloud`.

4.2 Questions

1. Write 1 paragraph describing your experience completing the the exercises.

Chapter 5

Friday Sept 18: Protection Island 1

The information below is taken from the following source: Newcomb, HR. 1940. Ring-necked pheasant studies on Protection Island in the Strait of Juan de Fuca, Washington. MS thesis. Oregon State University.

  a. Pheasant chicks are born during the summer.
  b. In May 1937, 10 pheasants were introduced to the island. Before the next breeding season there were 35 pheasants.
  c. November 10, 1938 a census estimated 110 pheasants.
  d. October 13, 1939 a census estimated 400 pheasants.

5.1 Questions

1. Read and complete all the exercises in Chapters 6.3 *Variables and assignment* to 6.10 *R packages* and 11 *Making graphs in R* of *Quantitative skills for biology*

HAND IN

- Answer all questions marked HAND IN in the reading

2. To make a graph of the data listed in b.-d., we need to learn how to work with dates. We will consider two possible approaches:

 i. Use a built-in `R` function to convert dates to a format that can be plotted (this question); and

 ii. Convert the dates to number of days since a reference date. Now the dates are numbers and these values can be plotted on the x-axis of a graph

(question 3).

In this question, we will proceed with option i. The function we will use is
`as.Date()`. You can learn how to use this function using an internet search or
by typing the following into your `Console`:

```
?as.Date
```

These files can be difficult to understand (see R Help files. A good way to
proceed is to experiment with the function in the `Console`. Try these:

```
as.Date(2012-01-31, format = %Y-%m-%d)
as.Date("2012-01-31", format = "%Y-%m-%d")
```

Note that only the second command is error-free. The first command fails
because the date argument for the `as.Date()` function must be a character
string, i.e., must be enclosed in `""` (see `?character`).

It is also possible to omit the format argument and just code: `as.Date("2012-01-31")`.
The help file notes that when the format argument is not specified, that formats
will be tried one by one and an error will be returned if none work. It is
advisable to specify the format, as allowing the function to infer the format
could introduce errors.

Chapter 6.9 Data structures describes how to make a vector (note a vector is a
list of numbers rather than just a single number). We need to make a vector of
the dates so that we can make our plot. For example,

```
x <- as.Date(c("2012-01-31", "2012-03-05", "2013-01-11"), format = "%Y-%m-%d")
```

Having completed Chapter 11 Making graphs in R, and having learned how to
work with dates, you should now be able to write an R script to make plot using
the information in b.-d. above.

HAND IN

- A graph and figure caption, which has dates on the x-axis and the pheasant
  population size on the y-axis drawing from the information provided in
  b.-d. You will need to guess the date of 'before the breeding season' as
  stated in b. and you should disclose the value of this guess in the figure
  caption. See 1.5.1 for more information.

- An R Script that produces the figure described above. See 1.5.2 for more
  information.

3. Next, we try approach ii. to make the graph. Under approach ii. we will
   work with the dates by converting them to the number of days since a
   reference date. To do this we will use the `julian()` function, which is part
   of the `chron` package.

Read Section 4.4 of Quantitative skills for biology regarding installing packages.
Install the package `chron` using either the `Install` button on the `Packages` tab,

or by using the command `install.packages("chron")` in the `Console` window. Note that the package is only available for use once you check the box on the `Packages` tab or by running the following command in the `Console`:

```
require("chron")
```

After the `chron` package is loaded, we can then query the `julian` function,

```
?julian
```

or use an internet search to better understand how to use it. As the help files can be difficult to understand, another approach to is to try out the function. Try the following:

```
julian(1,1,1970)
julian(1,2,1970)
julian(2,1,1970)
julian(1,1,1971)
julian(1,1,1969)
```

Which argument position of `julian()` function corresponds to the month? Note also that by default the origin (the origin is the value of 0) is set to January 1, 1970. Experiment by running the following lines of code:

```
julian(1,1,2000)
julian(1,1,2000, origin = c(1,1,1970))
julian(1,1,2000, origin = c(1,1,2000))
```

Finally, we need to make our figure. Recall that the plot function requires vectors of equal length for the x- and y-axes. Make a vector of the days since a reference as follows:

```
ref.day = c(1,1,2000)
x = c(julian(1,1,2000, origin = ref.day), julian(1,1,2002, origin = ref.day))
```

If you run into problems you can query the value of `x` in your console, and you can use `length(x)` to check the length of `x`.

HAND IN

- As for question 2. you need to hand in a graph with descriptive axes and with a figure caption. The y-axis on your graph is population size and the x-axis will be created using the `julian()` function. Be sure to label the x-axis differently than you did in question 2.

- You also need to produce an R Script that makes the figure described above. See 1.5.2 for more information. Name this file *protection-island-q3.R*

4. For the discrete time exponential (geometric) growth model, ideally the census points should be a fixed amount of time apart, i.e., a day, a week, or a year.

HAND IN

- Provide 1-3 sentences discussing the timing of the census points for Protection Island.

Chapter 6

Tues Sept 22: Protection Island 2

Here is some additional information also taken from: Newcomb, HR. 1940. Ring-necked pheasant studies on Protection Island in the Strait of Juan de Fuca, Washington. MS thesis. Oregon State University.

  a. Pheasant chicks are born during the summer.
  b. In May 1937, 10 pheasants were introduced to the island. Before the next breeding season there were 35.
  c. November 10, 1938 a census estimated 110 pheasants.
  d. October 13, 1939 a census estimated 400 pheasants.
  e. Between the 1938 and 1939 censuses, Newcomb observed that 17 adult birds died.
  f. During the 1938 nesting season: 5.86 eggs/nest. 83.57% of eggs hatched.
  g. During the 1939 nesting season: 8.73 eggs/nest. 64.58% hatched.
  h. During the 1939 nesting season: Average number of chicks per clutch was 6.93.[1]
  i. You can assume the sex ratio is 50:50 male to female. Pheasants are a sexually reproducing species.

[1] Note that g. and h. appear to be contradictory.

6.1 Questions

  1. Let d be the fraction of population that dies each year. What is d for the ring-tailed pheasant population on Protection Island? Write down any assumptions you have made.

2. b is the per capita number of births each year. What is the value of b? Write down any assumptions you have made.

3. Recall that $\lambda = 1 + b - d$. What is the value of λ? Is this population is exected to grow over time?

4. Lets assume that the pheasant population on Protection Island grows geoemetrically (i.e. exponentially) where the geometric growth rate, λ, is the value that you estimated in 5. Lets predict the population size each May beginning with May 1937. Let $N_0 = 10$ and let t be the number of years since May 1937. Recall that when a population grows geometrically,

$$N_t = N_0 \lambda^t$$

You can use `R` to do this calculation as follows (you should use your value of λ from question 5):

```
t <-1
NO <-10
lambda <-3
NO*lambda^t
```

where since $t = 1$ the result of `NO*lambda^t` is N_{t+1}, with $t = 1$, such that `NO*lambda^t` is the value of $N_{t+1} = N_2$: the population size two years after May 1937. You can change the value of t and repeat the calculation. Unless you have cleared your workshop it won't be necessary to re-input $N_0 = 10$ and $\lambda = 3$. As such, you can calculate N_3 with the following commands:

```
t <-2
NO*lambda^t
```

HAND IN

- Use `R` to predict the value of the pheasant population size every year up until May 1940.

7. The approach to calculating the pheasant population size in Question 6 is not very organized. In this question, we will learn how to make a data frame, use a for loop, and use the function `rbind()`.

Read Data structures in *Quantitative training for biology.*

Create a one row dataframe called `df`:

```
df <- data.frame(time = 0, popn.size = 10)
```

Query `df` in your `Console` to see the data frame you have created. We would like to add successive values of the population size that we calculate to the data frame. To do this we use the `rbind()` function, which binds rows together.

```
new.result <- data.frame(time = 1, popn.size = 20)
df <- rbind(df, new.result)
```

Here the `rbind()` function takes the `df` dataframe and adds the `new.result` data frame as a new row onto the bottom. Note that the code above *overwrites* the value of `df`: that is, `new.result` is added to the bottom of the `df` dataframe (containing only one row), and the result is called `df` (which now has two rows), and the old dataframe `df` (with one row) is overwritten. As such, each time you run the command `df <- rbind(df, new.result)` another row is added to `df`. Try the following:

```
new.result <- data.frame(time = 1, popn.size = 20)
df <- rbind(df, new.result)
df <- rbind(df, new.result)
df <- rbind(df, new.result)
```

If you query the value of `df` you can see that the several rows, all with identical values have been added because we have run the command `df <- rbind(df, new.result)` multiple times while the value of `new.result` is unchanged. Now let's change the value of `new.result` between each time we run the `df <- rbind(df, new.result)` command.

```
new.result <- data.frame(time = 1, popn.size = 20)
df <- rbind(df, new.result)
new.result <- data.frame(time = 2, popn.size = 30)
df <- rbind(df, new.result)
```

Finally, when we do calculations for a sequence of values, it is easier to code this using a `for` loop.

```
lambda <- 1.2
N0 <- 10
df <- data.frame(time = 0, popn.size = 10)
for(t in seq(1,4,1)){
  val <- N0*lambda^t
  new.result <- data.frame(time = t, popn.size = val)
  df <- rbind(df, new.result)
}
```

To understand the above code, after copy and pasting it into your `Console`, query the value of `df`: you should see predicted population sizes up until 4 years after May 1937. Now, lets try to understand `seq(1,4,1)`. Let's learn about the `seq()` function by trying it out in the `Console`. What is the result of each of these?

```
seq(-10,10)
seq(-10,5,0.1)
```

The `for` loop works by beginning with `t` equal to the first value of the sequence

and stepping through each value until the final value. The code is written so
that quantities that depend on `t` are inside the `for` loop (i.e., enclosed with in
the `{}` and those that do not depend on `t` are outside the `for` loop). Note that
`val` changes for different values of `t`, `new.result` changes for different values of
`t` (because `new.result` has `time = t` and `pop.size = val`, where `val` depends
on `t`). Finally, `df` also depends on `t`, because `new.result` depends on `t`. In
contrast, `N0` and `lambda` do not change with `t`, so it is more efficient to place
the allocated values for these parameters outside of the loop.

We can also plot the results of our calculations:

```r
lambda <- 2
N0 <- 10
df <- data.frame(time = 0, popn.size = 10)
for(t in seq(1,4,1)){
  val <- N0*lambda^t
  new.result <- data.frame(time = t, popn.size = val)
  df <- rbind(df, new.result)
}
plot(df$time, df$popn.size, typ = "l", xlab = "years since May 1937", ylab = "Populatio
```

If you already have an existing plot you can add new lines using `lines()`. For
example,

```r
plot(seq(1,4), c(1,3,4,2), ylab = "y-axis", xlab = "x-axis")
lines(seq(1,4), seq(1,4))
```
HAND IN

- Write an R scipt that builds on the file you have previously make *protection-island-q3.R*. Use the `lines()` command to add the predicted population size assuming geometric growth using the commands described in this section. If you have written the code correctly the result should look something like this:

```
ref.day = c(1,1,2000)
#x = c(julian(1,1,2000, origin = ref.day), julian(1,1,2002, origin = ref.day))
```

8. The geometric growth model is called 'discrete time'. This equation is appropriate for populations that have regular, pulse reproduction, for example, pheasants that reproduce once per year in the summer. Can you think of examples of other species that reproduce like this?

9. Can you think of any species that reproduce continuously throughout the year? These species are better modelled with a continuous time model.
